

Measuring Stream Flow and Deposition Along Copeland Creek

Irina Z. & Matt M.
Biology 314

Background

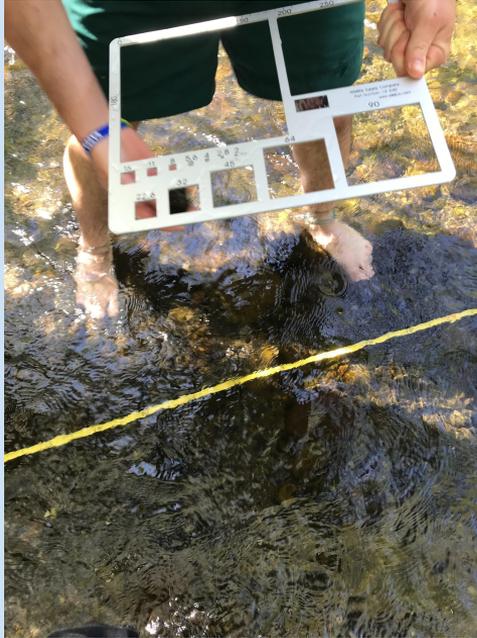

- Flowing water is an important mechanism for both erosion and deposition
- Stream- water velocity is affected by the size of sediment on the stream bed
- As water slows, larger particles are deposited. As the water slows even more, smaller particles are deposited.
- Information on bed-material particle size is important for streambed monitoring, analyzing stream habitat, and being able to predict/understand future stream behavior/processes

Experimental design

- To test whether there is a correlation between streamflow and size of particulates across the stream bed, we set up 5 Transects across a distance of $\sim 1,000\text{m}$, marking a transect at every 250ft (76.2m) in elevation.

Experimental design/Methods cont.

- We measured out from one side of the channel to the other, measuring cobble size at every 0.5 meters
- We also measured water depth at every 0.5 meters
- For flow rate, we used a hollow white ball which we timed floating down the creek 20ft (~6m) from our transect line.
- We used the following formula to calculate flow rate per second:

$$\text{Total width/Average Total Depth} = \text{Ft/s}^2$$

Experimental design/Methods cont.

ft³/sec

- 1) $1.05' \times 7.0' = 10.29 \text{ ft}^2$
- 2) $0.57' \times 16.4' = 9.348 \text{ ft}^2$
- 3) $0.59' \times 16.4' = 9.676 \text{ ft}^2$
- 4) $0.29' \times 16.4' = 4.756 \text{ ft}^2$
- 5) $0.20' \times 16.4' = 4.572 \text{ ft}^2$

A

- 1)
$$\text{Flow} = \frac{(10.29 \text{ ft}^2)(20 \text{ ft})(0.08)}{11.7 \text{ s}}$$

$$= 1.407 \text{ ft}^3/\text{sec}$$
- 2)
$$\frac{(9.348 \text{ ft}^2)(20 \text{ ft})(0.08)}{10.35 \text{ s}}$$

$$= 1.45 \text{ ft}^3/\text{sec}$$
- 3)
$$\frac{(9.676 \text{ ft}^2)(20 \text{ ft})(0.08)}{1.33 \text{ s}}$$

$$= 1.66 \text{ ft}^3/\text{sec}$$
- 4)
$$\frac{(4.756 \text{ ft}^2)(20 \text{ ft})(0.08)}{12.53 \text{ s}}$$

$$= 0.61 \text{ ft}^3/\text{sec}$$
- 5)
$$\frac{(4.572 \text{ ft}^2)(20 \text{ ft})(0.08)}{19.73 \text{ s}}$$

$$= 0.37 \text{ ft}^3/\text{sec}$$

Total width (a + b + c + d)

Total depth (a, + b, + c, + d.)

Total depth / 4 intervals for average depth

Measure 20 ft apart

Flow = $\frac{ALC}{T}$

A =
L = 20 ft
C = 0.08 (rocky bottom)
T = Time/# of trials

- check depth at each interval

Depth	width
1) $76 \text{ in} / 6 = 12.6 \text{ in} = 1.05'$	3 m = 9.8 ft
2) $68.3 \text{ in} / 10 = 6.83 = 0.57'$	5 m = 16.4 ft
3) $70.5 \text{ in} / 10 = 7.05 = 0.59'$	1)
4) $35 \text{ in} / 10 = 3.5 = 0.29'$	1)
5) $34 \text{ in} / 10 = 3.4 = 0.28'$	1)

$$\text{Flow} = ALC/T$$

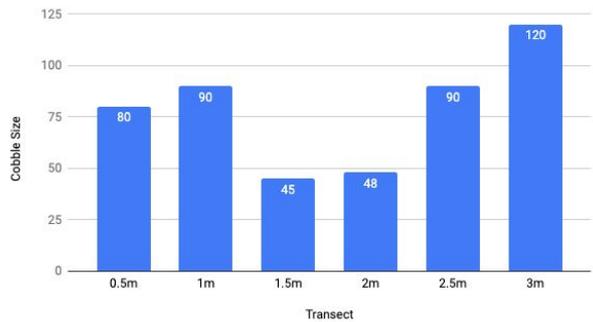

A = average cross sectional area of stream (width x depth)

L = length of stream (20 ft)

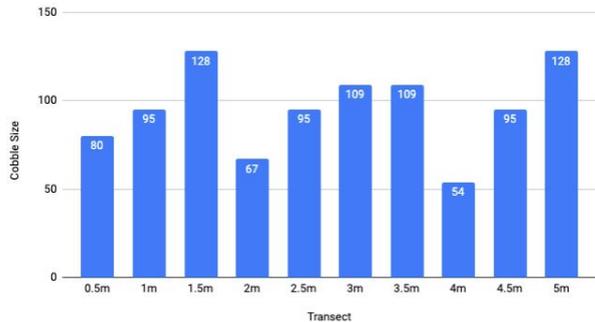

C = coefficient of stream bed (0.08 for rocky bottoms)

T = Time in s, to travel length of L

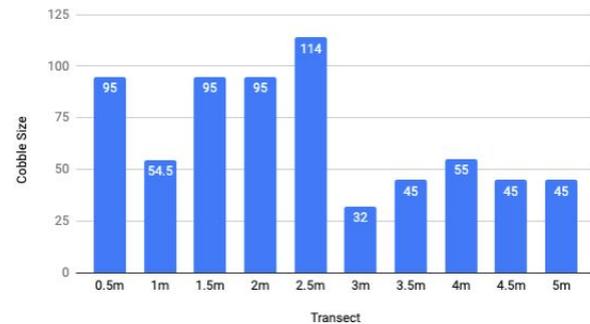

Cobble Size for Transect 1, in meters

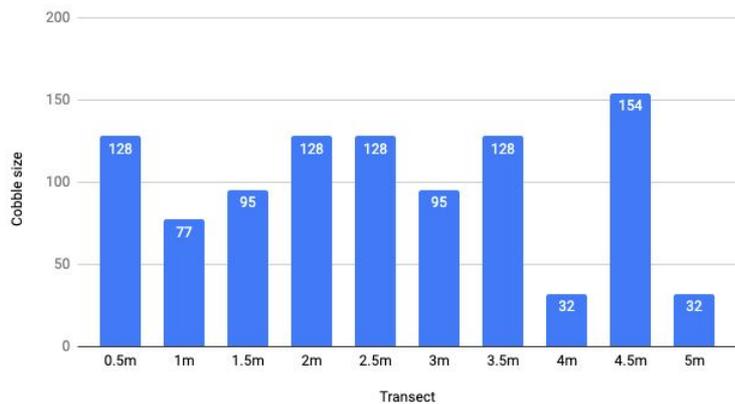

Cobble Size for Transect 2, in meters

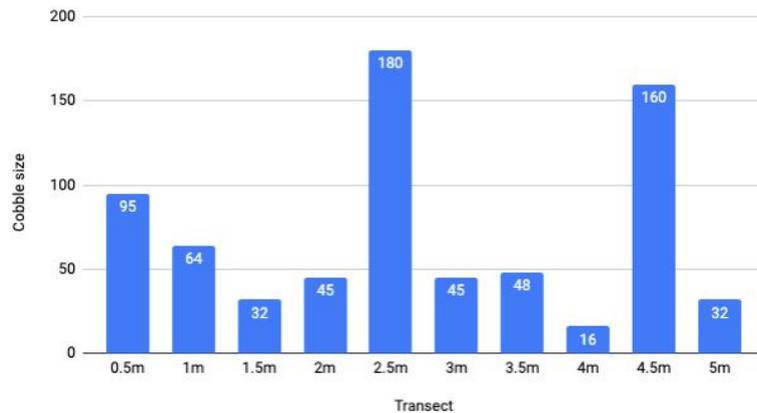

Cobble Size for Transect 3, in meters

Cobble Size at Transect 4, in meters

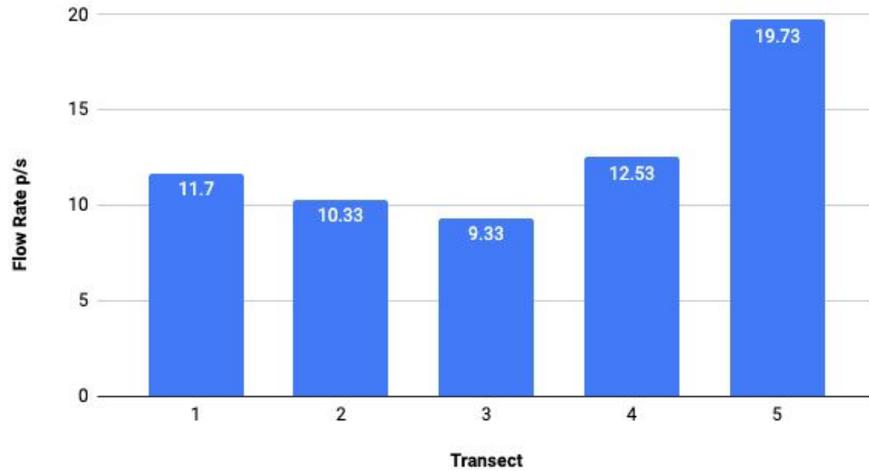

Cobble Size at Transect 5, in meters

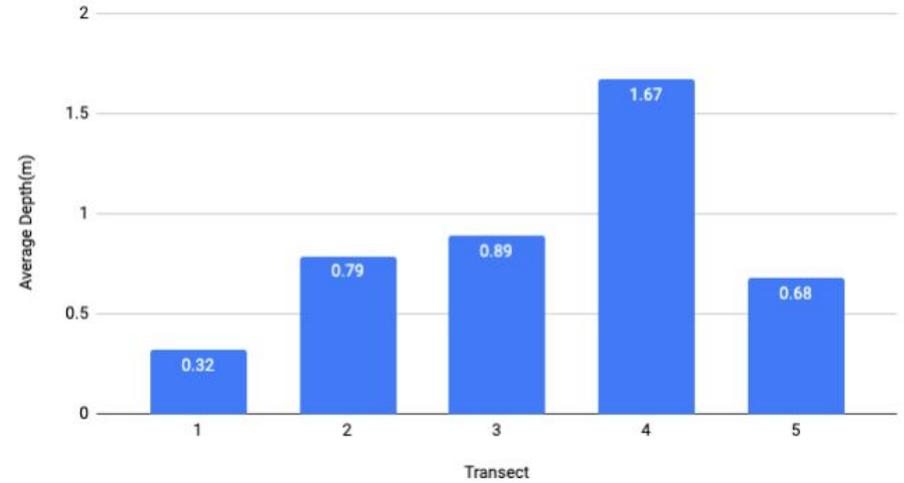

Data cont.

Flow Rate Transects 1-5 in seconds

Average Depth (m) for Transects 1-5

Analysis/Conclusion

- Correlation between faster flow rates and smaller cobble size
 - Transect 5 had the fastest flow rate and also had the smallest relative cobble size
 - Transect 4 displayed a similar pattern
 - Inversely Transects 2 and 3 had the two slowest flow rates, and displayed larger cobble sizes in their respective transects
- Overall trend of smaller cobble sized upstream (transect 5) in faster, higher elevated areas while there are larger cobble sizes in slower, lower elevated (transect 1) areas
